

Question When are two creatures of the form

equal as operators on invariants in $U(\mathfrak{g})$?

The answer must somehow be "if they are equal mod unitary link relations", whatever "unitary" might mean.

No, it comes out, "if they are conjugate via a unitary conjugator".

The classical story:

Why does "conjugation" imply "equality mod link relations"?

⇒ It does only for "unitary" conjugators!

Another moral:

It is not true that $\mathcal{D}(\text{links})$ is describable using link relations. Precisely, if

it does not imply that A & B are equivalent modulo x - & y -link relations!

Question what does it mean, knot-theoretically?
