

Start: An improved proof that in a HA, the antipode is an anti-homomorphism; i.e., that

$$\left. \right) \boxed{S} = \text{crossing with } \boxed{S} \text{ on both strands}$$

PF

$$\begin{aligned} \overset{a}{\curvearrowright} \square \square &= \curvearrowright \circlearrowleft \square = \text{crossing with } \boxed{S} \\ &= \text{crossing with } \boxed{S} \end{aligned}$$

(this is, with $c = (ab)^{-1}$)
 $a(bc) = e$

So

$$\begin{aligned} \square \square \overset{a^{-1}}{\curvearrowright} &= \text{crossing with } \boxed{S} \\ &= \text{crossing with } \boxed{S} \\ &= \text{crossing with } \boxed{S} \end{aligned}$$

multiply by a^{-1} on left.

re-associate

use antipode

$$\text{crossing with } \boxed{S} = "e \cdot (bc)"$$

$$\text{crossing with } \boxed{S} = \boxed{S}$$

$$\overleftarrow{S} \overrightarrow{S} = \text{bc} \quad \square$$

Now multiply by b^{-1} on the left

QED

Def A H.A. A is "top free" if ... 1. $A = V[h]$

missing details

2. $A \otimes A \rightarrow A \otimes A$

Def A is a deformation of A_0 if $A/hA = A_0$ as H.A.

Def A is a QUEA if $A/hA \cong U(\mathfrak{g})$ as H.A.

Claim Any B.A. H w/ $H/hH = A$ as B.A. has a unique compatible antipode making H a H.A. w/ $H/hH \cong A$ as H.A. } given $\begin{matrix} \cong \\ \text{H.A.} \\ A. \end{matrix}$

Subclaim $L: \text{End } A \rightarrow \text{End } A$ by $\left(\begin{matrix} A \text{ here is} \\ \cong \\ \text{H.A.} \end{matrix} \right)$

L_A is invertible & L_H is filtered, and the $\deg 0$ piece of L_H is L_A (the L of A)

\Rightarrow So L_H is invertible.

set $S_H = L^{-1}(1 \otimes \epsilon) \dots$ QED
