

Pensieve Header: A version of ρ_1 for links with some testing, by Roland.

Roland says: The determinant that gives Alexander for knots now computes the Alexander-specialization of the HOMFLYPT polynomial (normalized univariate Alexander for links). However this HOMFLY-specialization sometimes is 0 so that the matrix A of which we are computing the inverse for ρ_1 becomes singular. I suspect we should still be able to compute ρ_1 when A is singular like this but this requires a little more care.

APAI for links.

A version of Dror's Rot program that computes the rotation numbers from PD code of a link (the component containing edge 1 is assumed to be opened)

The output is a list of crossings each written as $\{\text{sign}, i, j, i^+, j^+\}$ and a list of rotation numbers for the edges. There are $2cr+1$ edges where cr is the number of crossings.

];
```

Except for the links Link[8,NonAlternating,8] and Link[9,NonAlternating,27]

The computation runs smoothly in all links in the table up to 9 crossings, see below.

We also interpreted the “Alexander” part of the output of rho in terms of the univariate Alexander for links computed below as a specialization of the Homfly polynomial (sometimes up to a multiplicative factor of T^{+1/2})

Interestingly the above specialization of the Homfly polynomial vanishes precisely on the two problematic links

Link[8,NonAlternating,8] and Link[9,NonAlternating,27]. This could help explaining why our rho fails to compute in these cases.
