The Strongest Genuinely Computable Knot Invariant in 2024

Abstract. "Genuinely computable" means we have computed it for random knots with over 300 crossings. "Strongest" means it separates prime knots with up to 15 crossings better than the less-computable HOMFLY-PT and Khovanov homology taken together. And hey, van der Veen it's also meaningful and fun.

Continues Rozansky, Garoufalidis, Kricker, and Ohtsuki, joint w- ge it goes through with (algebraic) probability ith van der Veen.

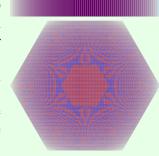

Acknowledgement. This work was supported by NSERC grant RGPIN-2018-04350 and by the Chu Family Foundation (NYC).

Strongest. Testing $\Theta = (\Delta, \theta)$ on prime knots up to mirrors and $\lim_{\text{diamondiraffic.com}} \operatorname{image credits:}$ reversals, counting the number of distinct values (with deficits in parenthesis): $(\rho_1: [Ro1, Ro2, Ro3, Ov, BV1])$

knots	(H, Kh)	(Δ, ρ_1)	$\Theta = (\Delta, \theta)$	together

Genuinely Computable. Here's Θ on a random 300 crossing knot (from [DHOEBL]). For almost every other invariant, that's science fiction.

Fun. There's so much more to see in 2D pictures than in 1D ones! Yet almost nothing of the patterns you see we know how to prove. We'll have fun with that over the next few years. Would you join?

Meaningful. θ gives a genus bound (unproven yet with confidence). We hope (with reason) it says something about ribbon knots.

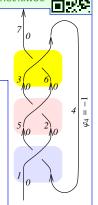

Conventions. T, T_1 , and T_2 are indeterminates and $T_3 := T_1 T_2$.

Preparation. Draw an n-crossing knot K as a diagram D as on the right: all crossings face up, and the edges are marked with a running index $k \in \{1, \dots, 2n + 1\}$ and with rotation numbers φ_k .

Model T Traffic Rules. Cars always drive forward. When a car crosses over a sign-s brid-

 $T^s \sim 1$, but falls off with probability $1 - T^s \sim 0$. At the very end, cars fall off and disappear. On various edges traffic counters are placed. See also [Jo, LTW].

age credit Dall-E

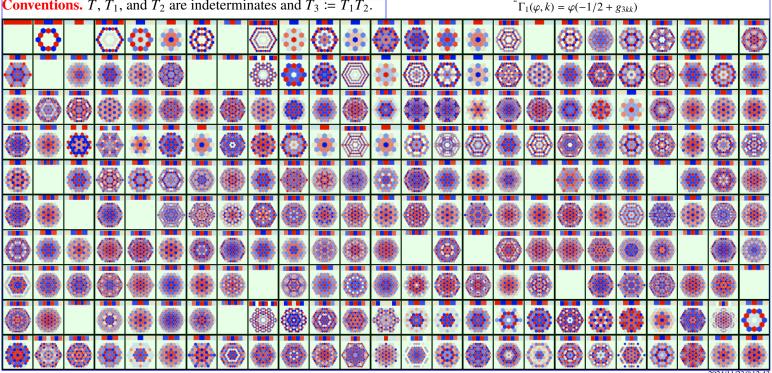

Definition. The traffic function $G = (g_{\alpha\beta})$ (also, the Green function or the two-point function) is the reading of a traffic counter at β , if car traffic

is injected at α (if $\alpha = \beta$, the counter is *after* the injection point). There are also model- T_{ν} traffic functions $G_{\nu} = (g_{\nu\alpha\beta})$ for $\nu =$ Example. 1, 2, 3.

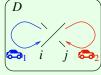

Don't Look.

$$\begin{split} R_{11}(c) &= s \left[1/2 - g_{3ii} + T_2^s g_{1ii} g_{2ji} - T_2^s g_{3jj} g_{2ji} - (T_2^s - 1) g_{3ii} g_{2ji} \right. \\ &+ (T_3^s - 1) g_{2ji} g_{3ji} - g_{1ii} g_{2jj} + 2 g_{3ii} g_{2jj} + g_{1ii} g_{3jj} - g_{2ii} g_{3jj} \right] \\ &+ \frac{s}{T_2^s - 1} \left[(T_1^s - 1) T_2^s \left(g_{3jj} g_{1ji} - g_{2jj} g_{1ji} + T_2^s g_{1ji} g_{2ji} \right) \right. \\ &+ (T_3^s - 1) \left(g_{3ji} - T_2^s g_{1ii} g_{3ji} + g_{2ij} g_{3ji} + (T_2^s - 2) g_{2jj} g_{3ji} \right) \\ &- (T_1^s - 1) (T_2^s + 1) (T_3^s - 1) g_{1ji} g_{3ji} \right] \\ R_{12}(c_0, c_1) &= \frac{s_1 (T_1^{s_0} - 1) (T_3^{s_1} - 1) g_{1ji_0} g_{3j_0i_1}}{T_2^{s_1} - 1} \left(T_2^{s_0} g_{2i_1i_0} + g_{2j_1j_0} - T_2^{s_0} g_{2j_1i_0} - g_{2i_1j_0} \right) \end{split}$$

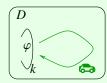

Theorem. With $c = (s, i, j), c_0 = (s_0, i_0, j_0), \quad s = 1$ and $c_1 = (s_1, i_1, j_1)$ denoting crossings, there is a quadratic $R_{11}(c) \in \mathbb{Q}(T_{\nu})[g_{\nu\alpha\beta} : \alpha, \beta \in \{i, j\}],$ a cubic $R_{12}(c_0, c_1) \in \mathbb{Q}(T_{\nu})[g_{\nu\alpha\beta}: \alpha, \beta \in \{i_0, j_0, i_1, j_1\}]$, and a **Conjecture 2.** On classical (non-virtual) knots, θ always has helinear $\Gamma_1(\varphi, k)$ such that the following is a knot invariant:

$$\theta(D) := \underbrace{\Delta_1 \Delta_2 \Delta_3}_{\text{normalization,}} \left(\sum_{c} R_{11}(c) + \sum_{c_0, c_1} R_{12}(c_0, c_1) + \sum_{k} \Gamma_1(\varphi_k, k) \right)$$
see later

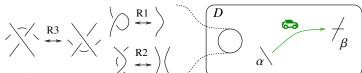

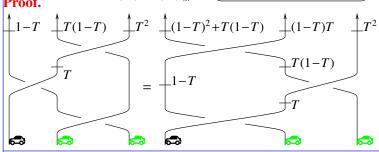

If these pictures remind you of Feynman diagrams, it's because they are Feynman diagrams [BN2].

Lemma 1. The traffic function $g_{\alpha\beta}$ is a "relative invariant":

Lemma 2. With $k^+ := k + 1$, the "g-rules" hold near a crossing c = (s, i, j):

 $g_{j\beta} = g_{j+\beta} + \delta_{j\beta}$ $g_{i\beta} = T^s g_{i+\beta} + (1 - T^s) g_{j+\beta} + \delta_{i\beta}$ $g_{2n+\beta} = \delta_{2n+\beta}$ $g_{\alpha i^{+}} = T^{s} g_{\alpha i} + \delta_{\alpha i^{+}} \quad g_{\alpha j^{+}} = g_{\alpha j} + (1 - T^{s}) g_{\alpha i} + \delta_{\alpha j^{+}} \quad g_{\alpha, 1} = \delta_{\alpha, 1}$ Corollary 1. G is easily computable, for AG = I (= GA), with A [DHOEBL] N. Dunfield, A. Hirani, M. Obeidin, A. Ehrenberg, S. Bhattacharythe $(2n+1)\times(2n+1)$ identity matrix with additional contributions:

$$c = (s, i, j) \mapsto \begin{array}{c|c} A & \operatorname{col} i^+ & \operatorname{col} j^+ \\ \hline \operatorname{row} i & -T^s & T^s - 1 \\ \operatorname{row} j & 0 & -1 \end{array}$$

For the trefoil example, we have:

$$A = \begin{pmatrix} 1 & -T & 0 & 0 & T - 1 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -T & 0 & 0 & T - 1 \\ 0 & 0 & 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & T - 1 & 0 & 1 & -T & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}$$

Note. The Alexander polynomial Δ is given by

 $\Delta = T^{(-\varphi - w)/2} \det(A),$ with $\varphi = \sum_{k} \varphi_{k}$, $w = \sum_{c} s$.

We also set $\Delta_{\nu} := \Delta(T_{\nu})$ for $\nu = 1, 2, 3$.

Questions, Conjectures, Expectations, Dreams.

What's the relationship between Θ and the Question 1. Garoufalidis-Kashaev invariants [GK, GL]?

xagonal (D_6) symmetry.

Conjecture 3. θ is the ϵ^1 contribution to the "solvable approximation" of the sl_3 universal invariant, obtained by running the quantization machinery on the double $\mathcal{D}(\mathfrak{b}, b, \epsilon \delta)$, where \mathfrak{b} is the Borel subalgebra of sl_3 , b is the bracket of b, and δ the cobracket. See [BV2, BN1, Sch]

Conjecture 4. θ is equal to the "two-loop contribution to the Kontsevich Integral", as studied by Garoufalidis, Rozansky, Kricker, and in great detail by Ohtsuki [GR, Ro1, Ro2, Ro3, Kr, Oh].

Fact 5. θ has a perturbed Gaussian integral formula, with integration carried out over over a space 6E, consisting of 6 copies of the space of edges of a knot diagram D. See [BN2].

Conjecture 6. For any knot K, its genus g(K) is bounded by the T_1 -degree of θ : $g(K) < \lceil \deg_{T_1} \theta(K) \rceil$.

Conjecture 7. $\theta(K)$ has another perturbed Gaussian integral formula, with integration carried out over over the space $6H_1$, consisting of 6 copies of $H_1(\Sigma)$, where Σ is a Seifert surface for K.

Expectation 8. There are many further invariants like θ , given by Green function formulas and/or Gaussian integration formulas. One or two of them may be stronger than θ and as computable.

Dream 9. These invariants can be explained by something less foreign than semisimple Lie algebras.

Dream 10. θ will have something to say about ribbon knots.
