

The Dogma is Wrong

Abstract. It has long been known that there are knot invariants associated to semi-simple Lie algebras, and there has long been a dogma as for how to extract them: “quantize and use representation theory”. We present an alternative and better procedure: “centrally extend, approximate by solvable, and learn how to re-order exponentials in a universal enveloping algebra”. While equivalent to the old invariants via a complicated process, our invariants are in practice stronger, faster to compute (poly-time vs. exp-time), and clearly carry topological information.

KiW 43 Abstract (omega-beta/kiw). Whether or not you like the formulas on this page, they describe the strongest truly computable knot invariant we know.

Experimental Analysis (omega-beta/Exp). Log-log plots of computation time (sec) vs. crossing number, for all knots with up to 12 crossings (mean times) and for all torus knots with up to 48 crossings:

Power. On the 250 knots with at most 10 crossings, the pair (ω, ρ_1) attains 250 distinct values, while (Khovanov, HOMFLY-PT) attains only 249 distinct values. To 11 crossings the numbers are (802, 788, 772) and to 12 they are (2978, 2883, 2786).

Genus. Up to 12 crossings, always ρ_1 is symmetric under $t \leftrightarrow t^{-1}$. With ρ_1^+ denoting the positive-degree part of ρ_1 , always $\deg \rho_1^+ \leq 2g - 1$, where g is the 3-genus of K (equality for 2530 knots). This gives a lower bound on g in terms of ρ_1 (conjectural, but undoubtedly true). This bound is often weaker than the Alexander bound, yet for 10 of the 12-xing Alexander failures it does give the right answer.

Ribbon Knots.

[Vo]: Works with $\mathcal{R} := \kappa(\tau^{-1}(1))$ for Alexander! $A^+ = -t^8 + 2t^7 - t^6 - 2t^4 + 5t^3 - 2t^2 - 7t + 13$
 $\rho_1^+ = 5t^{15} - 18t^{14} + 33t^{13} - 32t^{12} + 2t^{11} + 42t^{10} - 62t^9 - 8t^8 + 166t^7 - 242t^6 +$
Faster is better, leaner is meaner! $108t^5 + 132t^4 - 226t^3 + 148t^2 - 11t - 36$

dog·ma

n. pl. dog-mas or dog-ma-ta (-mā-tə)

The Free Dictionary, omega-beta/TFD

- 1. A doctrine or a corpus of doctrines relating to matters such as morality and faith, set forth in an authoritative manner by a religion.
- 2. A principle or statement of ideas, or a group of such principles or statements especially when considered to be authoritative or accepted uncritically: "Much education consists in the instilling of unfounded dogmas in place of a spirit of inquiry" (Bertrand Russell).

Theorem ([BNG], conjectured [MM], elucidated [Ro1]). Let $J_d(K)$ be the coloured Jones polynomial of K , in the d -dimensional representation of sl_2 . Writing

$$\left. \frac{(q^{1/2} - q^{-1/2})J_d(K)}{q^{d/2} - q^{-d/2}} \right|_{q=e^{\hbar}} = \sum_{j,m \geq 0} a_{jm}(K) d^j \hbar^m,$$

“below diagonal” coefficients vanish, $a_{jm}(K) = 0$ if $j > m$, and “on diagonal” coefficients give the inverse of the Alexander polynomial:

$$\left(\sum_{m=0}^{\infty} a_{mm}(K) \hbar^m \right) \cdot \omega(K)(e^{\hbar}) = 1.$$

“Above diagonal” we have **Rozansky’s Theorem** [Ro3, (1.2)]:

$$J_d(K)(q) = \frac{q^d - q^{-d}}{(q - q^{-1})\omega(K)(q^d)} \left(1 + \sum_{k=1}^{\infty} \frac{(q-1)^k \rho_k(K)(q^d)}{\omega^{2k}(K)(q^d)} \right).$$

The Yang-Baxter Technique. Given an algebra A (typically $\hat{\mathcal{U}}(\mathfrak{g})$ or $\hat{\mathcal{U}}_q(\mathfrak{g})$) and elements

$$R = \sum a_i \otimes b_i \in A \otimes A \quad \text{and} \quad C \in A,$$

$$\text{form} \quad Z = \sum_{i,j,k} C a_i b_j a_k C^2 b_i a_j b_k C.$$

Problem. Extract information from Z .
The Dogma. Use representation theory. In principle finite, but slow.

The Loyal Opposition. For certain algebras, work in a homomorphic poly-dimensional “space of formulas”.

$$m_k^{ij} \left(\curvearrowright \{ \mathcal{F}_S \} \xrightarrow{\mathbb{E}} \{ A^{\otimes S} \} \left(\curvearrowright m_k^{ij}$$

The (fake) moduli of Lie algebras on V , a quadratic variety in $(V^*)^{\otimes 2} \otimes V$ is on the right. We care about $sl_{17}^k := sl_{17}^{\epsilon} / (\epsilon^{k+1} = 0)$.

Why are “solvable algebras” any good? Contrary to common beliefs, computations in semi-simple Lie algebras are just awful:

```
In[1]:= MatrixExp[{{a b},{c d}}] // FullSimplify // MatrixForm [Enter]
```

Yet in solvable algebras, exponentiation is fine and even BCH, $z = \log(e^x e^y)$, is bearable:

```
In[2]:= MatrixExp[{{a b},{0 c}}] // MatrixForm [Enter]
Out[2]/MatrixForm=
{{e^a b (e^a - e^c)},{0 a - c e^c}}

In[3]:= MatrixExp[{{a1 b1},{0 c1}}].MatrixExp[{{a2 b2},{0 c2}}] //
MatrixLog // PowerExpand // Simplify //
MatrixForm [Enter]
```

Recomposing gl_n . Half is enough! $gl_n \oplus \mathfrak{a}_n = \mathcal{D}(\nabla, b, \delta)$:

Now define $gl_n^{\epsilon} := \mathcal{D}(\nabla, b, \epsilon \delta)$. Schematically, this is $[\nabla, \nabla] = \nabla$, $[\Delta, \Delta] = \epsilon \Delta$, and $[\nabla, \Delta] = \Delta + \epsilon \nabla$. In detail, it is

$$\begin{matrix} & i & j \\ i & \begin{matrix} e_{ij} \\ h_i \end{matrix} & \\ j & \begin{matrix} f_{ji} \\ g_j \end{matrix} & \end{matrix} \quad \begin{aligned} [e_{ij}, e_{kl}] &= \delta_{jk} e_{il} - \delta_{li} e_{kj} & [f_{ij}, f_{kl}] &= \epsilon \delta_{jk} f_{il} - \epsilon \delta_{li} f_{kj} \\ [e_{ij}, f_{kl}] &= \delta_{jk} (\epsilon \delta_{j < k} e_{il} + \delta_{il} (h_i + \epsilon g_i) / 2 + \delta_{i > l} f_{il}) \\ & - \delta_{li} (\epsilon \delta_{k < j} e_{kj} + \delta_{kj} (h_j + \epsilon g_j) / 2 + \delta_{k > j} f_{kj}) \\ [g_i, e_{jk}] &= (\delta_{ij} - \delta_{ik}) e_{jk} & [h_i, e_{jk}] &= \epsilon (\delta_{ij} - \delta_{ik}) e_{jk} \\ [g_i, f_{jk}] &= (\delta_{ij} - \delta_{ik}) f_{jk} & [h_i, f_{jk}] &= \epsilon (\delta_{ij} - \delta_{ik}) f_{jk} \end{aligned}$$

The sl_2 Example. Let $g^\epsilon = \langle h, e, l, f \rangle / ([h, \cdot] = 0, [e, l] = -e, [f, l] = f, [e, f] = h - 2\epsilon l)$ and let $g_k = g^\epsilon / (\epsilon^{k+1} = 0)$.

The Main g_k Theorem. The g_k -invariant of any S -component tangle T can be written in the form

$$Z(T) = \mathcal{O} \left(\omega e^{L+Q+P} : \bigotimes_{i \in S} e_i l_i f_i \right),$$

where ω is a scalar (meaning, a rational function in the variables h_i and their exponentials $t_i := e^{h_i}$), where $L = \sum a_{ij} h_i l_j$ is a balanced quadratic in the variables h_i and l_j with integer coefficients, where $Q = \sum b_{ij} e_i f_j$ is a balanced quadratic in the variables e_i and f_j with scalar coefficients b_{ij} , and where P is a polynomial in $\{\epsilon, e_i, l_i, f_i\}$ (with scalar coefficients) whose ϵ^d -term is of degree at most $2d + 2$ in $\{e_i, \sqrt{l_i}, f_i\}$. Furthermore, after setting $h_i = h$ and $t_i = t$ for all i , the invariant $Z(T)$ is poly-time computable.

The Main g_k Lemma. The following “re-ordering relations” hold:

$$\mathcal{O} \left(e^{\nu l + \beta e} : le \right) = \mathcal{O} \left(e^{\nu l + e' \beta e} : el \right) \quad (\text{and similarly for } fl \rightarrow lf),$$

$$\mathcal{O} \left(e^{\beta e + \alpha f + \delta e f} : fe \right) = \mathcal{O} \left(\nu e^{\nu(-\alpha \beta h + \beta e + \alpha f + \delta e f) + \lambda_k(\epsilon, e, l, f, \alpha, \beta, \delta)} : elf \right),$$

with $\nu = (1 + h\delta)^{-1}$ and where $\lambda_k(\epsilon, e, l, f, \alpha, \beta, \delta)$ is some fixed polynomial of degree at most $2k + 2$ in $\epsilon, e, \sqrt{l}, f, \alpha, \beta, \delta$, with scalar coefficients.
